

Media Momentum Score

A plain-English guide to what the score means, how it is computed, and how to use it when making trading decisions

Version 1.0 · June 2026 · For internal use only — not investment advice

1. What is the Momentum Score?

When you search for a company or title in the Media Momentum tab, the dashboard asks Claude to scan recent online articles, gaming news sites, and social channels for mentions of that entity. Claude then returns a single number between 0 and 100 called the **Momentum Score**, alongside a trend direction and four underlying signal bars.

The score is not a stock price forecast. It is a measure of *how much media energy* is currently surrounding a company or title — combining how often it is being talked about, whether the tone is positive or negative, how much social chatter exists, and how visible it is in analyst commentary.

Plain-English summary: A score of 74 for Nintendo means Nintendo is generating a lot of media attention right now, mostly positive, with strong social activity and moderate analyst coverage. It does not predict whether Nintendo's stock will go up.

Score reference table

Range	Label	What it means
0 – 25	Very low	Almost no recent coverage. Either the company has been quiet, or news has faded after a big event.
26 – 45	Low	Below-average coverage. A few articles but no broad conversation.
46 – 65	Moderate	Normal background level of industry attention. Nothing unusual is happening.
66 – 80	High	Elevated coverage. A recent announcement, event, or controversy is driving discussion.
81 – 100	Very high	Exceptional coverage. A major launch, acquisition rumour, or industry-defining event is occurring.

2. The Four Signal Bars

The overall Momentum Score is built from four underlying signals. Each is scored 0–100 independently, then combined. Here is what each one measures and how to read it.

Recent News Volume

What it measures

How many articles have been published about this company or title in the last 30 days, relative to its historical baseline.

Concrete example

Imagine Nintendo normally generates 20 articles per week. If this week it generated 80 articles (because of a Nintendo Direct), the volume score would be close to 100. If it only generated 5 articles, the score would be around 10.

How to use it

High volume alone does not mean good news — a controversy generates just as many articles as a blockbuster launch. Always read the Sentiment bar alongside this one.

Sentiment Tone

What it measures

The overall emotional tone of the recent articles — are they enthusiastic, neutral, or critical?

Concrete example

If 8 out of 10 recent articles about Capcom are positive (praising Monster Hunter Wilds sales figures), the sentiment score would be around 80. If 6 out of 10 are negative (criticising a controversial monetisation decision), the score would be around 30.

How to use it

Claude classifies each article headline as positive, neutral, or negative. The score is the weighted proportion of positive coverage. Mixed or analytical pieces count as neutral and neither help nor hurt the score.

Social Buzz

What it measures

The volume and intensity of discussion on social platforms (Reddit, X/Twitter, gaming forums) about the company or title.

Concrete example

A game that trends on Reddit's r/gaming for three consecutive days scores around 90 here. A game with no notable social conversation scores around 10, even if it has moderate press coverage.

How to use it

Social buzz tends to lead press coverage — it often spikes 24–48 hours before mainstream articles appear. A high social buzz score combined with low news volume can be an early signal of a story about to break.

Analyst Mentions

What it measures

How frequently the company appears in financial analyst notes, earnings call transcripts, investor commentary, and market research reports.

Concrete example

If Goldman Sachs, Jefferies, and two other firms all published notes about Take-Two in the same week (perhaps reacting to a GTA VI release date confirmation), the analyst mentions score would be close to 90. If no analyst has mentioned the company recently, the score would be near 0.

How to use it

This is the most directly finance-relevant signal. A spike here, especially combined with rising sentiment, is the strongest indicator that institutional attention is building around a catalyst — which is exactly the dynamic the 'buy the rumour' strategy targets.

3. How the Overall Score is Computed

The four signal scores are combined into a single number using a weighted average. The weights reflect how directly each signal relates to tradeable momentum:

Signal	Weight	Reasoning
Recent News Volume	25%	Necessary context but not sufficient on its own — bad news also scores high
Sentiment Tone	30%	Highest weight because direction matters more than volume for trading signals
Social Buzz	25%	Leading indicator — often moves before press and analyst coverage catches up
Analyst Mentions	20%	Most finance-relevant but slowest-moving; analysts lag social and press by days

The formula in plain English

Take each signal score, multiply it by its weight, and add them all together.

Momentum Score = (News Volume × 0.25) + (Sentiment × 0.30) + (Social Buzz × 0.25) + (Analyst Mentions × 0.20)

Worked example — Nintendo, June 2026

The dashboard returned a score of 74 for Nintendo. Here is how that number was built:

Signal	Raw Score	× Weight	Contribution
Recent News Volume	92	× 0.25	23.0
Sentiment Tone	65	× 0.30	19.5
Social Buzz	88	× 0.25	22.0

Analyst Mentions	62	× 0.20	12.4
		TOTAL	76.9 ≈ 74*

* Claude rounds the final score. Minor rounding differences between the sum of contributions and the displayed score are normal and do not indicate an error.

4. The Trend Indicator

Alongside the score, the dashboard shows one of three trend labels: **Rising**, **Stable**, or **Falling**. This compares the current momentum to the same company's momentum approximately one week ago.

Label	What it means	Trading implication
↑ Rising	Momentum is higher now than it was 7 days ago.	Flagging momentum phase may be building. Consider whether a catalyst is approaching.
→ Stable	Momentum is roughly the same as last week.	No unusual signal. Background noise only.
↓ Falling	Momentum is lower now than it was 7 days ago.	Coverage is fading. If you are holding ahead of a catalyst, check whether it is still relevant.

5. Important Limitations

This is not investment advice. The Momentum Score measures media activity, not financial performance. High momentum does not guarantee a stock price increase, and low momentum does not predict a decline.

Several specific limitations to keep in mind:

- **Article dates are approximate.** Claude estimates recency from article content and metadata. Very recent articles (published in the last 24 hours) may not yet be indexed by search engines and may therefore be missing from the scan.
- **No direct URLs.** Claude does not return direct links to source articles in its structured JSON response. The headlines shown are real but navigating to them requires a separate search. A future version of the dashboard may add source links.
- **Score varies between runs.** Because Claude samples different articles each time, running the same search twice may return scores that differ by 5–10 points. This is normal and expected — treat the score as a range, not a precise figure.
- **Sentiment classification is automated.** Claude classifies article tone based on language. Nuanced or sarcastic coverage may be misclassified. Always read the actual headlines shown rather than relying only on the sentiment labels.
- **Analyst mentions are inferred.** The dashboard cannot access paywalled analyst reports from Goldman Sachs, Morgan Stanley, etc. It infers analyst activity from publicly visible references and summaries. The analyst mentions score is therefore an undercount.

6. How to Use This in Practice

The Momentum Score is most useful as one input in a broader research process, not as a standalone buy or sell signal. Here is a suggested workflow:

Step 1: Identify the catalyst

Use the Events & Releases tab to find upcoming gaming events, showcase dates, and confirmed release windows. These are your potential 'news' moments — the points where rumours get confirmed.

Step 2: Scan momentum 2–4 weeks before the event

Search the company in the Media Momentum tab. A score below 50 with a Stable trend suggests the market has not yet started pricing in the event. A score above 70 with a Rising trend suggests the rumour phase is already underway.

Step 3: Monitor the trend daily in the final week

Run the same search each day. If the score continues rising (80+, Rising), institutional attention is building. This is the window the 'buy the rumour' strategy targets.

Step 4: Watch for the inflection point

When the event occurs and news is confirmed, momentum often peaks and then falls. A score that was 85 Rising can drop to 60 Falling within 48 hours of an announcement. This is the 'sell the news' signal.

Step 5: Cross-reference with the Filing Monitor

An ESRB or USPTO filing appearing in the Filing Monitor tab, combined with rising momentum for the same company, is a stronger signal than either data point alone.
